5. Login, Storage, and Data Model

Login Page

- Login.tsx handles both sign-in and account creation from the same card UI.
- It validates that the email contains @ and the password has at least 6 characters.
- The form uses the shared Input component, now with dark text/caret fixes so typed text remains visible.

Local Demo Auth

Data	Storage	Purpose
users	localStorage key	Stores demo user records by email/username.
currentUser	localStorage key	Stores the active signed-in user.
theme	localStorage key	Stores light/dark theme preference.
expenses	localStorage key read in App.tsx	The app initializes expenses from this key, while current expense updates are handled through React state.

Important security note

This login system is for a local/demo project. Passwords are stored directly in localStorage, so it is not safe for real users. A production version should use a backend auth service, hashed passwords, secure sessions, and a real database.

Expense Data Shape

- Expense fields: id, description, amount, category, date, optional notes, and aiSuggested.
- Dates are stored as YYYY-MM-DD strings and displayed with Intl.DateTimeFormat.
- Currency formatting uses Intl.NumberFormat with en-IN and INR.

6. AI and Receipt Scanning Features

AI Category Suggestions

- suggestCategory(description) tokenizes the description and compares it with category keyword lists.
- Supported categories include Food & Dining, Transportation, Shopping, Entertainment, Bills & Utilities, Healthcare, Education, Travel, and Other.
- The suggestion includes a category, confidence score, reason, matched signals, and a practical action tip.
- Example: Zomato or Swiggy signals map to Food & Dining with an action about separating eating-out spend from groceries.

AI Insights

- generateInsights calculates category concentration, weekly daily average, projected monthly spend, and practical spending tips.
- calculateCategoryTotals computes totals and percentages for charts.
