- Use a real backend and database for production, such as Node/Express or serverless APIs plus Postgres/Firebase/Supabase.
- Replace localStorage demo auth with secure authentication, hashed passwords, sessions/tokens, and protected user-specific data.
- Persist expense updates reliably per user. Current source initializes expenses from localStorage but manages changes in React state.
- Improve OCR with receipt image preprocessing, language/worker asset bundling, confidence scoring per field, and manual correction history.
- If true generative AI is needed, add an API-backed assistant for richer natural-language suggestions, budget plans, and anomaly detection.
- Consider packaging as Electron/Tauri later if a fully native app window, menu bar, offline asset control, and stronger desktop integration are required.
